The lumped-element model (also called lumped-parameter model, or lumped-component model) simplifies the description of the behaviour of spatially distributed physical systems into a topology consisting of discrete entities that approximate the behaviour of the distributed system under certain assumptions. It is useful in electrical systems (including electronics), mechanical multibody systems ...

In chemistry, an element is a pure substance consisting only of atoms that all have the same numbers of protons in their nuclei. Unlike chemical compounds, chemical elements cannot be broken down into simpler substances by any chemical reaction. The number of protons in the nucleus is the defining property of an element, and is referred to as its atomic number (represented by the symbol Z ...

- Define the element type(s) to be used (Chapter 6). - Define the material properties of the elements. - Define the geometric properties of the elements (length, area, and the like). - Define the element connectivities (mesh the model). - Define the physical constraints (boundary conditions). Define the loadings. • Solution

The matching text can appear directly within the selected element, in any of that element's descendants, or a combination Therefore it is not enough that you use :contains() selector , you also need to check if the text you search for is the direct content of the element you are targeting for, something like that:

The solution to the numerical model equations are, in turn, an approximation of the real solution to the PDEs. The finite element method (FEM) is used to compute such approximations. Take, for example, a function u that may be the dependent variable in a PDE (i.e., temperature, electric potential, pressure, etc.)

Detailed Explanation of the Finite Element Method (FEM)

The idea is to use bitwise operators for a solution that is $O(n)$ time and uses $O(1)$ extra space. The solution is not easy like other XOR-based solutions, because all elements appear an odd number of times here. The idea is taken from here. Run a loop for all elements in the array. At the end of every iteration, maintain the following two values.

I was getting this message for the <specFlow> element and therefore I added a specflow.xsd file to the solution this answer (with some modifications to allow for the <plugins> element). Thereafter I (like Pressacco), right clicked within the file buffer of app.config and selected properties, and within Schemas, I added "specflow.xsd" to the end.

`std::nth_element()` is an STL algorithm which rearranges the list in such a way such that the element at the n th position is the one which should be at that position if we sort the list. It does not sort the list, just that all the elements, which precede the n th element are not greater than it, and all the elements which succeed it are not less than it.
